

SMG Automotive - Backend Coding Challenge

This challenge is about showing us that you are a developer with a fast sense of perception and excellent analytical skills, but also that you are able to dive into and leverage modern technologies to create an awesome backend system.

Build a new Spring Boot service that will be part of a large distributed system and responsible for managing Products, with basic product data like name and price. The Product Service should offer a possibility to create a product. A large number of existing services, which are part of a distributed system, should be aware of newly created products in near real time.

Use Java 21, Spring Boot, PostgreSQL, and Kafka.

Watch your time and try to get as far as possible in about 5-8 hours of development. Create a well-defined scope for an MVP, wherein you can utilize our requirements as guidelines, while retaining the freedom to determine the significance of each requirement and decide which ones to implement, modify, or exclude.

Evaluation criteria:

- Well-defined scope of an MVP.
- Clean project setup and basic documentation (e.g. how to run it).
- Meaningful tests.
- Leveraging containers for running and testing the service.
